The proximal interphalangeal joints (middle knuckles of the fingers) are the most commonly injured joints in the hand. They are hinge joints and are capable of the largest range of movement. Injuries to these joints are often called finger sprains.

The tissues surrounding the joints include the ligaments and the joint capsule (which is an envelope surrounding the joint). The volar plate is a ligament which prevents the joint from over-straightening; but this is the one that gets injured the most.

The volar plate is damaged when force is applied to the finger causing too much movement to the joint, such as a ball hitting the end of the finger.

Varying degrees of injury can occur from tearing of the ligament, to a small chunk of bone pulling away from the main part of the bone.

**Treatment**
Initially a splint will be applied to the back of the finger to protect the joint and allow the bruising and swelling to settle. You will need to wear the splint for two weeks. Swelling can also be reduced with the use of compression bandages.

You will be shown bending exercises to do regularly. These will help get back movement while protecting the injury.
During your outpatient appointments, alternative splints, massage and exercises will be combined to restore movement and function.

While your injury is healing:
- Do not remove the splint
- Do not attempt to over-straighten the finger
- Do not carry out heavy tasks or contact sports
- Continue to maintain movement of your other fingers and use your hand for light activities.

If you have any questions or concerns about your exercises or your injury, please contact your occupational therapist on 01623 622515, extension 4271.

For appointment queries, please contact Therapy Services reception on 01623 622515, extension 3221.
